Module Summary

- A λ *expression* is a mechanism for specifying a *function object* or *functor* (Recall **Module 40**)
- The primary use for a λ is to specify a simple action to be performed by some function
- For example, consider a remainder operation **rem** that computes $m \% n$, that is, m modulo n . It has type `int -> int`. To write **rem** in C++, we define a function / functor:

```
int n = 7;
int rem(int m) // Function
    { return m % n; }
// Uses n in context
```

```
int n = 7;
struct remainder {                // Functor
    int mod;                      // State
    remainder(int n): mod(n) { }  // Ctor (n from context)
    int operator()(int m)        // Function call operator
    { return m % mod; }          // Body
};
```

```
rem(23); // 2
```

```
struct remainder rem(n);
rem(23); // 2
```

```
 $\lambda$ : auto rem = [n](int m) -> int { return m % n; } // Captures n from context
rem(23); // 2
```

- Note that `[n]` **Captures** n from context to close **rem** and create the **Closure Object** in C++

Practice Examples

Module Summary

- C++11 introduced λ 's as syntactically lightweight way to define functions on-the-fly
- λ 's can *capture* (or close over) variables from the surrounding scope – by *value* or by *reference*
- First consider callable things that do not capture any variables. C++ offers three alternatives:
 - **plain functions** (All versions of C & C++)
 - **functor classes** (C++03 onwards), and
 - **lambdas** (C++11 onwards)

```
#include <iostream> // cout
using namespace std;

int function (int a) { return a + 3; }
class Functor { public: int operator()(int a) { return a + 3; } };
auto lambda = [] (int a) { return a + 3; };

int main() { Functor functor;
    cout << function(5) << ' ' << functor(5) << ' ' << lambda(5) << endl;
}
8 8 8
```

- For plain functions that capture no variables, lambdas and functors behave the same

Mutability

Restrictions

Practice Examples

Module Summary

- A λ expression consists of the following:

```
[capture list] (parameter list) -> return-type { function body }
```

- The capture list and parameter list can be empty, so the following is a valid λ :

```
[] () { cout << "Hello, world!" << endl; }
```

- *Parameter list* is a sequence of parameter types and variable names as for an ordinary function
- *Function body* is like an ordinary function body
- If the *function body* has only one return statement (which is very common), the *return type* is assumed to be the same as the type of the value being returned
- If there is *no return statement* in the function body, the return type is assumed to be `void`

- Below λ has return type `void` – can be called without any use of the return value:

```
[] () { cout << "Hello from trivial lambda!" << endl; } ();
```

- However, trying to use the return type of the call is an error:

```
cout << [] () { cout << "Hello from trivial lambda!" << endl; } () << endl;
```

Capture

By Reference [&]

By Value [=]

Mutable

Restrictions

Practice Examples

Module Summary

- Below λ returns a `bool` value which is true if the first param is half of the second. The compiler knows the return type as `bool` from the return statement:

```
if ([](int i, int j) { return 2 * i == j; } (12, 24))  
    cout << "It's true!";  
else  
    cout << "It's false!";
```

- To specify return type:

```
cout << "This lambda returns " << [](int x, int y) -> int {  
    if(x > 5) return x + y;  
    else  
        if (y < 2) return x - y; else return x * y;  
} (4, 3) << endl;
```

- Below λ , returns an `int`, though the return statement provides a `double`:

```
cout << "This lambda returns " <<  
    [](double x, double y) -> int { return x + y; } (3.14, 2.7) << endl;
```

The output is `"This lambda returns 5"`

Closure Object

Lambdas vs. Closures

FCO

Anatomy

Parameters

Capture

By Reference [&]

By Value [=]

Mutable

Restrictions

Practice Examples

Module Summary

- Below λ *captures n by value* to compute the value of remainder of m :

```
int n = 7;  
auto rem = [n](int m) -> int { return m % n; };
```

- n is captured by $[n]$ (value – a copy is made from the context) at the time of constructing the closure object. Hence n *must be initialized before the construction* of the closure
- The *value of n cannot be changed* within the λ (for immutable λ 's)
- The changes to n after the construction of the closure object are not reflected

- Below λ *captures s by reference* to accumulate the value of m :

```
int s = 0;  
auto acc = [&s](int m){ s += m; };
```

- s is captured by $[&s]$ (reference – a reference is set to the context) at the time of constructing the closure object. Hence it is *optional to initialize s before the construction* of the closure. However, it must be initialized before the use of the closure
- The *value of s can be changed* within the λ
- The changes to s after the construction of the closure object will be reflected

Module Summary

● Closure

- A *closure* (*lexical* / *function closure*), is a technique for implementing *lexically scoped name binding* in a language with first-class functions
- Operationally, a closure is a *record storing a function* together with an *environment*
- The *environment* is a mapping associating (*binding*) each *free* variable of the function with the *value* or *reference* to which the name was bound when the closure was created
- *Unlike a plain function, a closure allows the function to access captured variables through the closure's copies of their values or references, even in its invocations outside their scope*

● Lambdas vs. Closures (From *Lambdas vs. Closures* by Scott Meyers, 2013)

- A λ expression `auto f = [&](int x, int y){ return fudgeFactor * (x + y); }` *exists only in a program's source code*. A lambda *does not exist at runtime*
- The runtime effect of a λ expression is the generation of an object, called *closure*
- Note that *f* is not the closure, it is a *copy of the closure*. The *actual closure object is a temporary* that's typically destroyed at the end of the statement
- Each λ expression causes a unique class to be generated (during compilation) and also causes an object of that class type – a closure – to be created (at runtime)
- Hence, *closures are to lambdas as objects are to classes*

Restrictions

Practice Examples

Module Summary

- A **λ -expression** generates a **Closure Object** at *run-time*
- A closure object is *temporary*
- A closure object is *unnamed*
- For a λ -expression, the compiler creates a *functor class* with:
 - *data members*:
 - ▷ a value member each for each value capture
 - ▷ a reference member each for each reference capture
 - a *constructor* with the captured variables as parameters
 - ▷ a value parameter each for each value capture
 - ▷ a reference parameter each for each reference capture
 - a *public inline const function call operator()* with the parameters of the lambda as parameters, generated from the body of the lambda
 - *copy constructor*, *copy assignment operator*, and *destructor*
- A *closure object* is constructed as an instance of this class and *behaves like a function object*
- A λ -expression without any capture behaves like a function pointer

Module Summary

- The *captures* is a comma-separated list of zero or more captures, optionally with default
- The capture list defines the outside variables that are accessible from the λ function body
- The only capture defaults are
 - [&] (implicitly capture the used automatic variables *by reference*) and
 - [=] (implicitly capture the used automatic variables *by copy / value*)
- The *current object* (**this*) can be *implicitly captured* if either capture default is present
- If implicitly captured, it is always captured by reference, even for [=]. Deprecated since C++20

Capture	Meaning	C++
<code>identifier</code>	simple by-copy capture	C++11
<code>identifier ...</code>	simple by-copy capture that is a <i>pack expansion</i>	C++11
<code>identifier init</code>	by-copy capture with an <i>initializer</i>	C++14
<code>& identifier</code>	simple by-reference capture	C++11
<code>& identifier ...</code>	simple by-reference capture that is a <i>pack expansion</i>	C++11
<code>& identifier init</code>	by-reference capture with an <i>initializer</i>	C++14
<code>this</code>	simple by-reference capture of the current object	C++11
<code>*this</code>	simple by-copy capture of the current object	C++17
<code>... identifier init</code>	by-copy capture with an <i>initializer</i> that is a <i>pack expansion</i>	C++20
<code>& ... identifier init</code>	by-reference capture with an <i>initializer</i> that is a <i>pack expansion</i>	C++20

λ in C++

Syntax and Semantics

Closure Object

Lambdas vs. Closures

FCO

Anatomy

Parameters

Capture

By Reference [&]

By Value [=]

Mutable

Restrictions

Practice Examples

Module Summary

Wrong Capture by Reference

- Closures may outlive their creating function

```
std::function<bool(int)>
returnClosure(int a) { // returns bool
    int b, c;
    ...
    // won't compile, but assume it would
    return [] (int x)
        { return a*x*x + b*x + c == 0; };
}
```

```
// f is essentially a copy of
// lambda's closure
auto f = returnClosure(10);
...
if (f(22)) // invoke the closure
```

- What are the values of **a**, **b**, **c** in the call?
 - `returnClosure` no longer active!
- Non-static locals referenceable only if **captured**

Correct Capture by Reference

- This version has no such problem

```
int a; // now at global or namespace scope
std::function<bool(int)>
returnClosure() {
    static int b, c; // now static ...

    // now compiles
    return [] (int x)
        { return a*x*x + b*x + c == 0; };
}
```

```
// as before

auto f = returnClosure();
...
if (f(22)) // as before
```

- a**, **b**, **c** outlive `returnClosure`'s invocation
- Variables of static storage duration always referenceable

Module Summary

- Consider

```
int h = 10;
auto two_h = [=] () { h *= 2; return h; };
std::cout << "2h:" << two_h() << " h:" << h << std::endl;
```

error C3491: 'h': a by-value capture cannot be modified in a non-mutable lambda

- λ closure objects have a *public inline function call operator* that:

- Matches the parameters of the lambda expression
- Matches the return type of the lambda expression
- Is declared `const`

- Make mutable*

```
int h = 10;
auto two_h = [=] () mutable { h *= 2; return h; };
std::cout << "2h:" << two_h() << " h:" << h << std::endl;
```

Module Summary

- Will this compile? If so, what is the result?

```
struct foo {  
    foo() : i(0) { }  
    void amazing(){ [=]{ i = 8; }(); } // i is captured by value  
                                        // Can it be changed without mutable?  
  
    int i;  
};  
foo f;  
f.amazing();  
std::cout << "f.i : " << f.i;
```

Output: f.i : 8

- this implicitly captured
- i actually is `this->i` which can be written from a member function as a data member. So no **mutable** is required

Capture: Restrictions

Module M52

Partha Pratim Das

Objectives & Outlines

λ in C++

Syntax and Semantics

Closure Object

Lambdas vs. Closures

FCO

Anatomy

Parameters

Capture

By Reference [&]

By Value [=]

Mutable

Restrictions

Practice Examples

Module Summary

- Capture restrictions

- Identifiers must only be listed once

```
[i,j,&z]() {...} // Okay
```

```
[&a,b]() {...} // Okay
```

```
[z,&i,z]() {...} // Bad, z listed twice
```

- Default by value, explicit identifiers by reference

```
[=,&j,&z]() {...} // Okay
```

```
[=,this]() {...} // Bad, no this with default =
```

```
[=,&i,z]() {...} // Bad, z by value
```

- Default by reference, explicit identifiers by value

```
[&,j,z]() {...} // Okay
```

```
[&,this]() {...} // Okay
```

```
[&,i,&z]() {...} // Bad, z by reference
```

- Scope of Capture

- Captured entity must be defined or captured in the immediate enclosing lambda expression or function

Closure Object: Capture: Mixed Examples

Module M52

Objectives & Outlines

λ in C++

Syntax and Semantics

Closure Object

Lambdas vs. Closures

FCO

Anatomy

Parameters

Capture

By Reference [&]

By Value [=]

Mutable

Restrictions

Practice Examples

Module Summary

```
class A { std::vector<int> values; int m_;  
public: A(int mod) : m_(mod) { }  
    A& put(int v) { values.push_back(v); return *this; }  
    int extras() { int count = 0;  
        std::for_each(values.begin(), values.end(),  
            [=, &count](int v){ count += v % m_; });  
        return count;  
    }  
};  
A g(4);  
g.put(3).put(7).put(8);  
std::cout << "extras: " << g.extras();
```

extras: 6

- Capture default by value
- Capture `count` by reference, accumulate, return
- How do we get `m_`?
- Implicit capture of `'this'` by value
