Staff Salary Processing: New C Solution

Staff Salary Processing: C++ Solution

C and C++ Solutions: A Comparison

Virtual Function Pointer Table

Module Summary

- Understood type casting – implicit as well as explicit – for built-in types, unrelated types, and classes on a hierarchy
- Understood the notions of upcast and downcast
- Understood Static and Dynamic Binding for Polymorphic type
- Understood **virtual** destructors, Pure Virtual Functions, and Abstract Base Class
- Designed the solution for a staff salary processing problem using iterative refinement – starting with a simple C solution and repeatedly refining finally to an easy, efficient, and extensible C++ solution based on flexible polymorphic hierarchy

Virtual Function Pointer Table

Module Summary

- An organization needs to develop a salary processing application for its staff
- At present it has an engineering division only where **Engineers** and **Managers** work. Every **Engineer** reports to some **Manager**. Every **Manager** can also work like an **Engineer**
- The logic for processing salary for **Engineers** and **Managers** are different as they have different salary heads
- In future, it may add **Directors** to the team. Then every **Manager** will report to some **Director**. Every **Director** could also work like a **Manager**
- The logic for processing salary for **Directors** will also be distinct
- Further, in future it may open other divisions, like Sales division, and expand the workforce
- **Make a suitable extensible design**

C and C++ Solutions: A Comparison

Virtual Function Pointer Table

Module Summary

- In Module 29, we have developed a flat C Solution using *function switch*
- In Module 30, we refined the C Solution to develop two types of C++ Solution using
 - Non-polymorphic hierarchy - employing *function switch*
 - Polymorphic hierarchy - employing *virtual function*
- In Module 29, we had mentioned that in the flat C Solution it is not easy to use function pointers as the processing functions `void ProcessSalaryEngineer(Engineer *)`, `void ProcessSalaryManager(Manager *)`, and `void ProcessSalaryDirector(Director *)` all have different types of arguments and therefore a common function pointer type cannot be defined
- We can work around this by:
 - Passing the staff object as `void *`, instead of `Engineer *`, `Manager *`, or `Director *`
 - Cast it to respective object type in the respective function. That is, cast to `Engineer *` in `ProcessSalaryEngineer(Engineer *)` and so on
 - We can then use a function pointer type `void (*)(void *)`
- We illustrate in the Solution

Staff Salary Processing: New C Solution

Staff Salary Processing: C++ Solution

C and C++ Solutions: A Comparison

Virtual Function Pointer Table

Module Summary

- **Advantages**

- Solution exists!
- Code is well structured – has patterns

- **Disadvantages**

- Employee data has scope for better organization
 - ▷ No encapsulation for data
 - ▷ Duplication of fields across types of employees – possible to mix up types for them (say, `char *` and `string`)
 - ▷ Employee objects are created and initialized dynamically through `Init...` functions. How to release the memory?
- Types of objects are managed explicitly by `E_Type`:
 - ▷ Difficult to extend the design – addition of a new type needs to:
 - Add new type code to `enum E_Type`
 - Add a new pointer field in `struct Staff` for the new type
 - Add a new case (`if-else` or `case`) based on the new type: **Removed using function pointer**
 - ▷ Error prone – developer has to decide to call the right processing function for every type (`ProcessSalaryManager` for `Mgr` etc.): **Removed using function pointer**
- Unable to use Function Pointers as each processing function takes a parameter of different type - no common signature for dispatch

- **Recommendation**

- Use classes for encapsulation on a hierarchy

Virtual Function Pointer Table

How do virtual functions work?

Module M31

Partha Pratim Das

Weekly Recap

Objectives & Outline

Staff Salary Processing: New C Solution

Staff Salary Processing: C++ Solution

C and C++ Solutions: A Comparison

Virtual Function Pointer Table

Module Summary

- The C Solution with function pointers gives us the lead to implement virtual functions. Here
 - We have used an array of function pointers (`psFuncPtr psArray[]`) to keep the processing functions (`void ProcessSalaryEngineer(Engineer *)`, `void ProcessSalaryManager(Manager *)`, and `void ProcessSalaryDirector(Director *)`) indexed by the type tag (`enum E_TYPE { Er, Mgr, Dir }`)
 - In C++, every class is a separate type - so the tag can be removed if we bind this table (**Virtual Function Table** or **VFT**) with the class
 - Every class can have a VFT with its appropriate processing function pointer put there
 - By override, all these functions can have the same signature (`void ProcessSalary()`) and can be called through the same expression (`(Engineer *)->ProcessSalary()`)
- We now illustrate Virtual Function Table through simple examples to show how does it work for inherited, overridden and overloaded member functions

C and C++ Solutions: A Comparison

Virtual Function Pointer Table

Module Summary

- Whenever a class defines a **virtual** function a hidden member variable is added to the class which points to an array of pointers to (**virtual**) functions called the **Virtual Function Table (VFT)**
- VFT pointers are used at run-time to invoke the appropriate function implementations, because at compile time it may not yet be known if the base function is to be called or a derived one implemented by a class that inherits from the base class
- VFT is class-specific – all instances of the class has the same VFT
- VFT carries the **Run-Time Type Information (RTTI)** of objects

C and C++ Solutions: A Comparison

Virtual Function Pointer Table

Module Summary

- Leveraging an innovative solution to the Salary Processing Application in C using function pointers, we compare C and C++ solutions to the problem
- The new C solution with function pointers is used to explain the mechanism for dynamic binding (polymorphic dispatch) based on **virtual** function tables
